Rhodium-Catalyzed C-H Functionalization-Based Approach to Eightmembered Lactams

Shangze Wu, Rong Zeng, Chunling Fu, Yihua Yu, Xue Zhang, and Shengming Ma*a,b

Received (in XXX, XXX) Xth XXXXXXXXX 20XX, Accepted Xth XXXXXXXX 20XX 5 DOI: 10.1039/b000000x

A Rh(III) catalyzed formal [4+2+2] cyclization of N-pivaloyloxy benzamides 1 with 1,6-allene-enes 2 by C-H functionalization is reported. The reactions occur at room temperature and are compatible with air and moisture with a tolerance of many synthetically useful functional groups. The follow-up modifications of the products have been demonstrated. After careful mechanistic studies and DFT 10 calculation, a reaction mechanism was proposed.

It is well known that medium-sized rings are hard to synthesize due to entropic and enthalpic reasons. Among them, eightmembered lactams are found in many natural products and 15 bioactive molecules.² The normal approach to these molecules often require harsh conditions (such as high temperatures and highly diluted solutions), at least stoichiometric amount of metal reagents, or pre-functionalized starting materials by several steps.³ Therefore, developing a catalytic procedure for the 20 efficient synthesis of eight-membered lactams under mild conditions is still desired.

In principle, [2+2+2+2] or [4+2+2] cyclization would be the most straightforward yet challenging approach to the eightmembered lactams.⁴ On the other hand, in recent years, directed 25 Rh(III)-catalyzed C-H functionalization reactions have been extensively studied.⁵ Among them, the formal [4+2]-cyclization between arenes or alkenes with a proper directing group and unsaturated compounds such as alkenes, alkynes or allenes facilely affording six-membered products have been well 30 established. 6-12 We envisioned a strategy for the efficient construction of eight-membered rings if a [2+2]-atom component, i.e., a molecule contains two unsaturated carbon-carbon bonds, is applied instead of alkenes, alkynes or allenes. The challenge is the highly unfavorable selectivity for the formation eight-35 membered ring since it is much easier to form six-membered rings (A' vs. B) with the participation of just one C-C π -bond (Scheme 1). Herein, we wish to report the realization of such a concept by applying an allene-ene as the [2+2]-atom component catalyzed by [Cp*RhCl₂]₂ with N-pivaloyloxy benzamides as the 40 [4]-atom component under very mild conditions.

Scheme 1 Rh(III)-catalyzed cyclization: [4+2] vs [4+2+2]

Results and Discussion

After some trial and error with compounds bearing at least two 45 unsaturated C-C bond, we identified such a reaction, in which 3-(trimethylsilyl)-1,2,6-heptatriene 2a acts as a [2+2]-atom component while N-pivaloyloxybenzamide 1a behaves as the [4]atom component. When 1a was treated with 2a in a mixed solvent of MeOH and water (v/v 20/1) under the catalysis of 50 [Cp*RhCl₂]₂, the expected [4+2+2] cyclization product, i.e., the benzo-fused eight-membered lactam 3a, was indeed formed in 75% NMR yield although together with the [4+2] regioisomeric mixture¹³ of two products **4aa** and **5aa** with the isolated carboncarbon double bond being reacted as the minor products (Table 1, 55 Entry 1). The structure of 3a was confirmed by X-ray diffraction study (Scheme 2),14 indicating that the allene unit has been reacted first. After screening the solvent, we found that MeOH was the best (Table 1, Entries 1-5). Moisture, air and 4Å MS had very little influence on the yield (Table 1, Entries 6-7). Then, the 60 base effect was investigated and 30 mol% of K2CO3 was found to be the optimal (Table 1, Entries 2 and 8-13). Control experiments showed that no reaction occurred in the absence of [Cp*RhCl₂]₂ or bases. Finally, the reaction of 1a and 2a in methanol under the catalysis of [Cp*RhCl₂]₂ with 30 mol% K₂CO₃ as base at room 65 temperature was chosen as the optimal reaction conditions for further study (Table 1, Entry 11).

The reaction was conducted with 1a (0.2 mmol), 2a (0.2 mmol), 5 [Cp*RhCl₂]₂ (0.004 mmol), K₂CO₃ (0.06 mmol), MeOH (1.2 mL) and monitored by TLC. b Determined by H NMR using dibromomethane as internal standard. c The ratio of MeOH/H2O was 20/1 (1.2 mL/ 0.06 mL). ^d Under N₂ atmosphere. ^e Under N₂ atmosphere and 4 Å MS was added. ^f Isolated yield is in the bracket. g Recovery of 1a was 98% with 2a 10 disappeared. h 10 mol% K2CO3 was added. i 50 mol% K2CO3 was added. j 1 equiv. K₂CO₃ was added. ^k The reaction was conducted in the absence of the Rh(III) catalyst.

15 Scheme 2 ORTEP representation of 3aa

When the reaction was conducted on a gram-scale, 3aa was also formed in 62% yield (Table 2, Entry 2). The reaction of substrates with electron-donating groups such as methyl, tert-

butyl and methoxy or electron-withdrawing groups such as 20 COOMe, Cl, Br, CF₃ and NO₂ in the para position of the aryl unit all gave corresponding lactams 3ba-3ia in moderate to good yields, showing the potential for further elaboration (Table 2, Entries 3-10); when o-methyl N-pivaloyloxy benzamide 1j was used, lactam 3ja could also be formed in a lower yield (23%) 25 with full conversion, most probably due to the steric effect (Table 2, Entry 11). It is important to note that silyl group could be replaced with aryl groups with either electron-withdrawing or electron-donating substituents, a hetero-aryl and even an alkyl group, showing the broad substrate scope (Table 2, Entries 12-30 16). The structure of **3ae** was further confirmed by X-ray diffraction study (see p 26 in the Supporting Information). 15 It should be noted that 4- and 5-type by-products were also formed as by-products as judged by ¹H NMR analysis (Table 2).

Furthermore, when the reaction of 1a was conducted in [D₄]methanol under the standard conditions in the absence of or 20 presence of allene-ene 2a, no obvious deuterium incorporation was detected from the recovered 1a and formed 3aa, suggesting that the C–H activation step was irreversible (Scheme 4, a and b). Then the kinetic isotope effect (KIE) value of 1a and 1a-d₅ was measured by parallel experiments. The high KIE value of 12.3 25 demonstrated that C-H activation must be involved in the ratedetermining step (Scheme 4, c).¹⁶

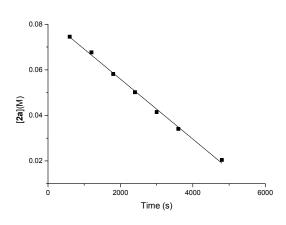

Scheme 4 Mechanistic studies

The orders of each reactant were also measured. A linear 30 relationship was observed for ln([1a]) vs. reaction time, indicating a first-order dependence of the reaction rate with 1a $[\ln(\mathbf{1a})]$ =-kt+ $\ln(\mathbf{1a_0})$ (y=a+b×x in Scheme 5). A zero-order with the allene moiety 2a ($[2a]=-kt+[2a_0]$) ($y=a+b\times x$ in Scheme 6) was also determined by the linear relationship of [2a] vs. 35 reaction time. Thus, the rate equation for this reaction is d[3aa] $/dt = k[1a]^{1}[2a]^{0}$.

Scheme 5 The determination of the order with 1a

Shemical Science Accepted Manu

Scheme 6 The determination of the order with 2a

According to the experimental results above, a plausible 5 mechanism has been proposed as shown in Scheme 7. Firstly, [Cp*Rh(CO₃)] was formed to be the catalytic species from the [Cp*RhCl₂]₂ dimer and CO₃². Then base-promoted C-H bond rhodation would form rhodacyclic intermediate Int 1, 5-12 which is followed by the insertion of the allene moiety in the 1,6-allene-10 ene 2a, affording seven-membered rhodacycle Int 2.17 Subsequent cyclic carborhodation of the terminal C-C double bond would yield nine-membered rhodacyclic intermediate Int 3 (Int 3'). The N-pivaloyloxy containing intermediate Int 3 (R = 1). Piv) would undergo reductive elimination to form the final 15 [4+2+2] product **3aa**. Alternatively, the *N*-methoxy intermediate Int 3' (R = Me) leads exclusively to the methylenecyclopentene product 7aa by β -H elimination (Scheme 3, c). Thus, it is concluded that the OPiv group is important since the coordination of the carbonyl oxygen atom in the Piv group of **Int 3** with Rh(III) 20 makes a coordination-saturated stable 18e complex, which must have prevented the β -H elimination, avoiding the formation of 7aa-type product.¹⁸

Scheme 7 A possible mechanism

25 Follow-up modifications of the Products

N-Protected eight-membered benzolactams have been found to be bioactive as dopamine D₃ receptor ligands. ²ⁱ Thus, product **3aa** has been treated with 1-(3-chloropropyl)-4-(p-methoxyphenyl) piperazine to afford the analogue 9 in 75% yield (Scheme 8, a). 30 To further demonstrate the synthetic applications of the products, the functionalization of the TMS group in 3aa had been conducted: a) desilylation product 10 could be formed in 63% yield by treating 3aa with TiCl₄ in DCM for 16 h. ^{17c,19} b) The TMS group of 3aa could be transformed to synthetically useful 35 vinyl iodide 11,20 which will be useful for any elaboration based on cross coupling reactions (Scheme 8, b).

Scheme 8 Follow-up modifications of the products

Theoretical Studies on Mechanism

DFT calculations have been performed, using 3-methyl-1,2,6heptatriene (2a') as the model of substrate 2a and Nacetoxybenzamide (1a') as the model of N-pivaloyloxybenzamide 1a, in which the TMS group in 2a and the tertiary butyl group in Open Access Article. Published on 05 February 2015. Downloaded on 07/02/2015 06:20:50

1a have both been replaced with the methyl group (eq. 3). We believe that the catalytic species involved in this reaction is a carbonate-ligated species, Cp*Rh(CO₃), which may be generated via Rh dimer dissociation and ligand exchange from [Cp*RhCl₂]₂ 5 and K₂CO₃. The energetic profiles for the initial steps of the C-H activation and the subsequent carborhodations are provided in Figure 1. The initial formation of the complex IN1 (selected as the free energy reference) involves the coordination of the nitrogen atom in N-acetoxybenzamide substrate (2a') with the Rh 10 center of Cp*Rh(CO₃), which would be followed by the deprotonation of the N-H unit by the CO₃². This N-H deprotonation step is computed to require a 12.2 kcal/mol activation barrier (TS1) to afford the N-metalated intermediate IN2, which is 4.5 kcal/mol less stable than the precursor IN1. 15 Subsequently, IN2 isomerizes to a more stable intermediate IN3, in which the Rh...Ohydroxyl coodination in IN2 is replaced with the Rh Ocarbonyl coordination, with a free energy of 6.6 kcal/mol lower than the starting point (IN1).

The following aryl C-H activation step is realized by a concerted metalation/deprotonation (CMD) process^{21a-k} termed as ambiphilic metal ligand activation (AMLA))211 via a six-membered cyclic transition state TS2, in which the Rh-C bond formation occurs simultaneously with the deprotonation of 25 the ortho aromatic proton to afford the rhoda-cyclic intermediate IN 4. This CMD step is computed to feature the highest relative energy barrier of the whole profile (20.8 kcal/mol, TS2, Figure 1) and may, thus, be rate-determining. This calculated prediction is in consistent with the results of the above mentioned kinetics and 30 deuterium exchange experiments (Schemes 3-6).

The dissociation of H₂CO₃ from IN4 and the coordination of the allene moiety in the 1,6-allene-ene 2a' affords IN5 with a relative energy of 4.0 kcal/mol lower than the starting point. Then the coordinated distal allenic double bond undergoes an insertion 35 into the Rh-C bond via TS3 to provide the seven-membered rhodacycle intermediate IN6, in which the N-acetoxy moiety coordinates to Rh center with the pendant carbonyl oxygen. This cyclic carborhodation step is computed to be exergonic ($\Delta G_{sol} = -$ 11.4 kcal/mol) and requires a 14.7 kcal/mol activation barrier 40 (TS3, Figure 1).

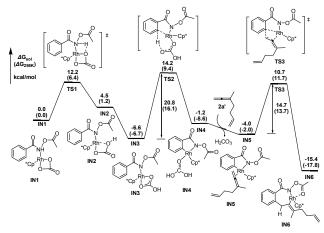

Figure 2 The energetic profiles for the C-H activation and the carborhodations of IN1

According to the experimental results, the [4+2] regioisomeric 45 products 4aa and 5aa are obtained as the minor byproducts simultaneously with the desired [4+2+2] product 3aa. To validate the selectivity, the pathways for the competing insertion of the isolated carbon-carbon double with either direction into the Rh-C bond have also been calculated, which are depicted in Scheme 9. 50 The two competing insertion pathways are realized via TS3' and TS3", respectively, with similar activation energy barriers of over 17 kcal/mol, which are about 2.5 kcal/mol higher than TS3, indicating that the terminal allenic double bond is more reactive than the isolated double bond in this insertion step. So the 55 terminal allenic double bond is calculated to carborhodate preferentially, which is in accordance with experimental observations of 4aa and 5aa as minor by-products.

Scheme 9 The activation free energies of forming 4aa' and 5aa'

From the seven-membered rhodacycle IN6, subsequent second insertion of the terminal C-C double bond is a key step for the formation of the final eight-membered lactam 3aa product. Besides the second cyclic carborhodation pathway, the possibility of other competitive pathways, such as C-N bond formation and 65 β -H elimination from **IN6**, are also be investigated. The energetic profiles for possible reactions from **IN6** are presented in Figure 2. To facilitate the second cyclic carborhodation, the sevenmembered rhodacycle IN6 should first isomerize to the more stable intermediate IN7 (11.7 kcal/mol lower in energy than IN6). 70 in which the Rh center coordinates with the terminal C-C double bond instead of the carbonyl moiety in IN6. Then the subsequent insertion of the terminal C-C double bond into the Rh-C bond occurs via TS4 with an activation barrier of 9.1 kcal/mol. This step is exergonic with the generation of the nine-membered

rhodacyclic intermediate IN8, which is also stabilized by the coordination of the pendant carbonyl oxygen in the N-acetoxy moiety with the Rh center.

The activation free energy of direct reductive elimination from 5 IN6 is computed to be 35.5 kcal/mol (TS5, Figure 2), indicating that this direct C-N formation step is not favorable kinetically. Based on the mechanistic investigations of a closely related systems,²² a more kinetically favorable pathway of C-N formation from IN6 is discovered through a high oxidation state 10 Rh(V) nitrene species IN9,23 generated by the migration of the acetoxy moiety form N to Rh via a five-membered transition state (TS6, Figure 2). This migration step is computed to be slightly endergonic ($\Delta G_{sol} = 6.8 \text{ kcal/mol}$) and requires a 13.8 kcal/mol activation barrier (TS6). The nitrene Rh(V) species IN9 has a 15 Rh=N distance of only 1.867 Å, which is much shorter than the Rh-N single bond distance of 2.162 Å in IN8. The following reductive elimination of nitrene Rh(V) species IN9 is much easier with a barrier of only 7.7 kcal/mol via TS7, affording IN10 irreversibly with high exergonicity. Overall, the activation energy 20 for the C-N bond formation pathway from IN6 is 14.5 kcal/mol, as defined by the energy gap between TS7 and IN6.

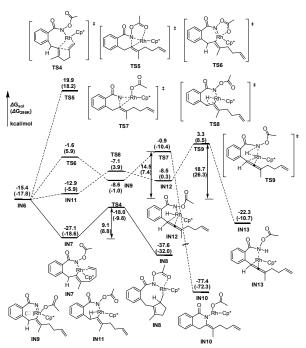

Figure 2 The energetic profiles for possible cyclic carborhodation, C-N bond formation and β -H elimination pathways from **IN6**

Another competitive pathway from **IN6** is the β -H elimination process, affording the allenation product. In this step, IN6 should first isomerize into **IN11** (Figure 2), in which the β -H coordinates with the Rh center to be perfectly oriented for elimination, with the free energy increased by about 2.5 kcal/mol. The β -H 30 elimination occurs subsequently via TS8 with an activation barrier of 5.8 kcal/mol, leading to rhodium hydride species **IN12**, which is slightly higher in energy by 4.4 kcal/mol than the corresponding precursor (IN11). However, the following reductive elimination of the rhodium hydride species IN12 is not 35 as facile as the β -H elimination. This reductive elimination step is computed to require an activation barrier of 11.8 kcal/mol (TS9,

Figure 2). Hence, it should overcome an activation energy of 18.7 kcal/mol totally for the allenation product generation, which is the free energy gap between TS9 and IN6.

Thus, as can be deduced from the energetic data mentioned above, the second cyclic carborhodation pathway forming the nine-membered rhodacyclic intermediate IN8 ($\Delta G_{sol}^{\neq} = 9.1$ kcal/mol) is the most kinetically favorable among the several alternative pathways from IN6, which is in well agreement with 45 the experimental observations.

Continuing with the favorable pathway from the ninemembered rhodacyclic intermediate IN8, there are also two competitive pathways, forming the final [4+2+2] product 3aa' by reductive elimination and the methylenecyclopentene product 50 **7aa'** by β -H elimination, respectively. The energetic profiles of both possible pathways from IN8 are presented in Figure 3 for comparison.

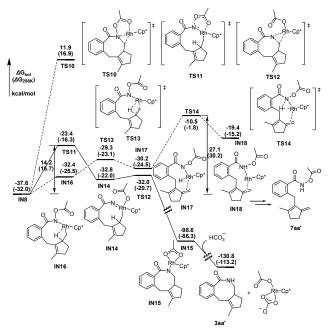

Figure 3 The energetic profiles for possible C-N bond formation and β-H 55 elimination pathways from IN8.

Similar with the about mentioned C-N formation pathway from **IN6** (Figure 2), the migration of the acetoxy moiety from N to Rh occurs prior to the C-N bond formation, generating a high oxidation state Rh(V) nitrene intermediate IN14, which is 4.8 60 kcal/mol higher in energy than the precursor (**IN8**, Figure 3). This migration step is realized via a five-membered trasition sate TS11, overcoming an activation barrier of 14.2 kcal/mol. Then subsequent reductive elimination of the nitrene Rh(V) species IN14 is very facile via TS12 with a barrier of only 0.8 kcal/mol, 65 exergonic largely by over 68 kcal/mol, to form the eightmembered ring in IN15. Then the protonolysis of the N atom of IN15 by HCO₃ would regenerate the catalytically active species Rh(III) and yield the final product 3aa', with an overall exergonicity of 130 kcal/mol.

For the β -H elimination process from **IN8** (Figure 3), isomerization of IN8 into IN16 should occur first, with the free energy increased by 5.2 kcal/mol, which is caused by the less stability of C-H."Rh coordination in IN16 than Ocarbonyl."Rh

This article is licensed under a Creative Commons Attribution-NonCommercial 3.0 Unported Licence

Open Access Article. Published on 05 February 2015. Downloaded on 07/02/2015 06:20:50

coordination in IN8. In the following step, rhodium hydride species IN17 would be formed by β -H elimination of IN16 via TS13 with an activation barrier of only 3.1 kcal/mol. The subsequent reductive elimination of the rhodium hydride species 5 IN17 is highly energy demanding via TS14, hence, raising the barrier of the whole β -H elimination process of **IN8** to 27.1 kcal/mol, which is 12.9 kcal/mol higher than the alternative C-N bond formation pathway. Therefore, the final [4+2+2] product are obtained experimentally, instead of the 7-type 10 methylenecyclopentene product 7aa'. Thus, the whole catalytic cycle for the [4+2+2] cyclization

Thus, the whole catalytic cycle for the [4+2+2] cyclization mechanism is completed by DFT calculations. Shown in Figure 4 is the reaction coordinate of the most kinetically favorable pathway involving N-H deprotonation/ CMD activation of C-H bond/ first carborhodation of the distal allenic double bond/ second cyclic carborhodation of the isolated carbon-carbon double/ C-N bond formation steps. As can be deduced from the energetic data in Figure 4, the [4+2+2] cyclization reaction is calculated to occur irreversibly, as the final eight-membered lactam product lies over 122 kcal/mol below the starting point, and the CMD C-H bond activation is the rate-limiting step, with the highest relative energy barrier of 20.8 kcal/mol (TS2), which agrees well with the observations of the kinetics and deuterium exchange experiments (Schemes 3-6).

To further elucidate the influence of the N-OR moiety on the

reaction, we also investigated the possible pathways from the Nmethoxy containing intermediate IN8 Me. Figure 5 presents the free energy profiles for the favored pathway of β -H elimination and other two competitive possibilities. IN8_Me should first 30 isomerize to **IN16 Me**, in which the β -H atom has an agostic interaction with the Rh center and be well oriented for the following elimination. The subsequent β -H elimination step leads to the rhodium hydride species IN17_Me via TS13_Me, with a barrier of only 5.1 kcal/mol. The subsequent reductive 35 elimination breaks the Rh-H bond and forms the N-H bond simultaneously by overcoming a free energy barrier of 21.5 kcal/mol (TS14 Me) to afford IN18 Me. Thus, the overall β -H elimination process of IN8 Me is facile, with a 24.6 kcal/mol activation barrier. What's more, the direct C-N bond forming 40 process from IN8 Me via TS10 Me with an even higher activation barrier of 53.8 kcal/mol, could be ruled out safely. And the similar intramolecular oxidation of the Rh(III) species **IN8** Me to Rh(V) nitrene intermediate by the migration of the N-OMe moiety via a three-center TS is also highly energy 45 demanding (39.7 kcal/mol, **TS11_Me**). Therefore, the *N*-methoxy containing intermediate IN8 Me leads to the 7-type methylenecyclopentene product by β -H elimination exclusively (Scheme 3c).

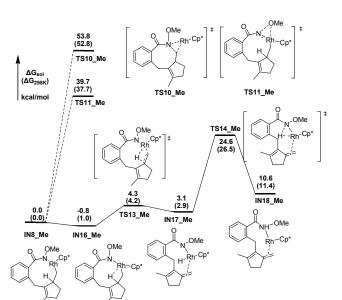

Figure 5 The energetic profiles for the β -H elimination pathway from

We concluded that the key factor of the influence of the N-OR 5 moiety on the reaction selectivity could be attributed to the extra coordination of the carbonyl oxygen in the N-acetoxy moiety with the Rh center in IN8. First of all, this extra coordination in IN8 facilitates the migration of the acyloxy from N to Rh, thus enable the formation of the high oxidation state Rh(V) nitrene 10 intermediate IN14 (Figure 3), which is the C-N bond formation precursor. Secondly, the extra stabilization of IN8 by this kind of coordination increases the barrier of the whole β -H elimination process in the N-acetoxy containing system, avoiding the formation of the 7-type mthylenecyclopentene product.

15 Conclusions

In conclusion, we have developed the first [Cp*RhCl₂]₂catalyzed [4+2+2] cyclization between N-pivaloyloxy benzamides and 1,6-allene-enes forming eight-membered lactams. These reactions proceed at room temperature and are compatible 20 with ambient air and moisture. Many arenes and allene-enes with many synthetically useful functional groups are compatible in the reactions. After careful mechanistic studies and DFT calculation, the reaction mechanism was presented in deatail and the role of the N-OR moiety on the selectivity for the formation of the final 25 products is also unveiled. The formed lactams have been transformed to cyclic vinylic iodide or desilylated product as well as the analogue of dopamine D₃ receptor. With easy availability of both starting materials and new concept to facilely synthesize the 8-membered rings, which are otherwise hard to construct by 30 other means, this [4+2+2] cyclization protocol will be of high interest in organic chemistry and related disciplines. Further studies involving three or more components and chiral [4+2+2]

reaction are being carried out in our laboratory.

Experimental Section

Materials: [Cp*RhCl₂]₂ was purchased from Strem. Npivaloyloxy benzamides were prepared according to the literature procedures.^{7c,7o} Grignard reagents were prepared from the corresponding aryl halides and magnesium. Other commercially available chemicals were purchased and used without additional 40 purification unless noted otherwise. ¹H NMR spectra were recorded on a Bruker-300 MHz spectrometer (except for 2h, a Bruker-700 MHz spectrometer was used) and ¹³C NMR spectra were recorded at 75 MHz. All ¹H NMR experiments were measured with tetramethylsilane (0 ppm) or the signal of residual 45 CHCl3 (7.26 ppm) in CDCl₃ as the internal reference, ¹³C NMR experiments were measured in relative to the signal of CDCl₃ (77.0 ppm), and ¹⁹F NMR experiments were measured in relative to the signal of residual CFCl₃ (0 ppm) in CDCl₃.

Typical Procedure for the [4+2+2] Cyclization Reactions: 50 To a dried Schlenk tube equipped with a Teflon-coated magnetic stirring bar were added N-pivalovloxybenzamide 1a (221.6 mg, 1 mmol), [Cp*RhCl₂]₂ (12.7 mg, 0.02 mmol), K₂CO₃ (41.3 mg, 0.3 mmol), 3-(trimethylsilyl)-1,2,6-heptatriene 2a (166.0 mg, 1 mmol), and MeOH (6 mL) sequentially at rt. After being stirred 55 for 2 h, the reaction was complete as monitored by TLC. Filtration through a short column of silica gel (eluent: MeOH) and evaporation afforded the crude product, which was purified by flash column chromatography on silica gel (eluent: dichloromethane/ethyl acetate = 4/1) to afford 3aa (194.1 mg, 60 68%): solid; m.p. 188.2-188.9 °C (hexane/ethyl acetate); ¹H NMR (300 MHz, CDCl3) δ 7.77-7.65 (m, 1 H, NH), 7.48-7.33 (m, 2 H, Ar-H), 7.29 (t, J = 6.2 Hz, 2 H, Ar-H), 3.80 (d, J = 13.5 Hz, 1 H, one proton of CH_2), 3.46 (d, J = 13.2 Hz, 1 H, one proton of CH_2), 3.26-3.10 (m, 1 H, one proton of NCH₂), 2.96-2.75 (m, 2 H, one 65 proton of NCH₂ + CH), 2.39-2.16 (m, 2 H, CH₂), 1.98-1.85 (m, 1 H, one proton of CH₂), 1.14-0.94 (m, 1 H, one proton of CH₂), 0.26 (s, 9 H, 3 × CH₃); 13 C NMR (75 MHz, CDCl₃) δ 173.9, 150.6, 137.6, 137.2, 134.6, 130.3, 129.2, 127.4, 126.8, 52.0, 46.5, 35.7, 34.9, 28.9, -0.07; IR (neat, cm⁻¹) 3291, 3187, 3063, 2945, 70 2852, 1660, 1604, 1460, 1446, 1404, 1353, 1338, 1248, 1048, 1038, 1003; MS (EI, 70 eV) m/z (%) 286 (M⁺+1, 18.79), 285 (M⁺, 62.45), 256 (100), 255 (100), 73 (100); Anal. Calcd for $C_{17}H_{23}NOSi$ (MW = 285.5): C 71.53, H 8.12, N 4.91. Found: C 71.50, H 8.14, N 4.73.

Computational Methodology. All calculations were performed with the Gaussian 09 program.²⁴ Geometries have been fully optimized with the density functional theory of M06 method.^{25,26} The standard 6-31G(d,p)²⁷ basis set was used for carbon, hydrogen, nitrogen and oxygen atoms and LANL2DZ 80 basis set²⁸ with effective core potential (ECP) for rhodium. Harmonic vibration frequency calculations were carried out for all the stationary points to confirm each structure being either a minimum (no imaginary frequency) or a transition structure (one
